$$\frac{dx}{dt} = -\nabla f(x)$$

 Simplified analyses. The gradient flow has no step-size, so all the traditional annoying issues regarding the choice of step-size, with line-search, constant, decreasing or with a weird schedule are unnecessary.

Puc. 1: ■Source

- Simplified analyses. The gradient flow has no step-size, so all the traditional annoying issues regarding the choice of step-size, with line-search, constant, decreasing or with a weird schedule are unnecessary.
- Analytical solution in some cases. For example, one can consider quadratic problem with linear gradient, which will form a linear ODE with known exact formula.

- Simplified analyses. The gradient flow has no step-size, so all the traditional annoying issues regarding the choice of step-size, with line-search, constant, decreasing or with a weird schedule are unnecessary.
- Analytical solution in some cases. For example, one can consider quadratic problem with linear gradient, which will form a linear ODF with known exact formula
- Different discretization leads to different methods. We will see, that the continuous-time object is pretty rich in terms of the variety of produced algorithms. Therefore, it is interesting to study optimization from this perspective.

1. Simplest proof of monotonic decrease of GF:

$$\frac{d}{dt}f(x(t)) = \nabla f(x(t))^{\intercal} \frac{dx(t)}{dt} = -\|\nabla f(x(t))\|_2^2 \leqslant 0.$$

If f is bounded from below, then f(x(t)) will always converge as a non-increasing function which is bounded from below. It is straightforward, that GF converges to the stationary point, where $\nabla f = 0$ (potentially including minima, maxima and saddle points).

1. Simplest proof of monotonic decrease of GF:

$$\frac{d}{dt}f(x(t)) = \nabla f(x(t))^{\intercal} \frac{dx(t)}{dt} = -\|\nabla f(x(t))\|_2^2 \leqslant 0.$$

If f is bounded from below, then f(x(t)) will always converge as a non-increasing function which is bounded from below. It is straightforward, that GF converges to the stationary point, where $\nabla f = 0$ (potentially including minima, maxima and saddle points).

2. If we additionaly have convexity:

$$f(x) \geqslant f(y) + \nabla f(y)^\top (x-y) \qquad \Rightarrow \qquad \nabla f(y)^\top (x-y) \leqslant f(x) - f(y)$$

1. Simplest proof of monotonic decrease of GF:

$$\frac{d}{dt}f(x(t)) = \nabla f(x(t))^{\intercal} \frac{dx(t)}{dt} = -\|\nabla f(x(t))\|_2^2 \leqslant 0.$$

If f is bounded from below, then f(x(t)) will always converge as a non-increasing function which is bounded from below. It is straightforward, that GF converges to the stationary point, where $\nabla f = 0$ (potentially including minima, maxima and saddle points).

2. If we additionaly have convexity:

$$f(x) \geqslant f(y) + \nabla f(y)^\top (x-y) \qquad \Rightarrow \qquad \nabla f(y)^\top (x-y) \leqslant f(x) - f(y)$$

3. Finally, using convexity:

$$\frac{d}{dt} \big[\|x(t) - x^*\|^2 \big] = -2(x(t) - x^*)^\top \nabla f(x(t)) \leqslant -2 \big[f(x(t)) - f^* \big]$$

1. Simplest proof of monotonic decrease of GF:

$$\frac{d}{dt}f(x(t)) = \nabla f(x(t))^{\top} \frac{dx(t)}{dt} = -\|\nabla f(x(t))\|_2^2 \leqslant 0.$$

If f is bounded from below, then f(x(t)) will always converge as a non-increasing function which is bounded from below. It is straightforward, that GF converges to the stationary point, where $\nabla f=0$ (potentially including minima, maxima and saddle points).

2. If we additionaly have convexity:

$$f(x) \geqslant f(y) + \nabla f(y)^\top (x-y) \qquad \Rightarrow \qquad \nabla f(y)^\top (x-y) \leqslant f(x) - f(y)$$

3. Finally, using convexity:

$$\frac{d}{dt}[\|x(t) - x^*\|^2] = -2(x(t) - x^*)^\top \nabla f(x(t)) \leqslant -2[f(x(t)) - f^*]$$

4. Leading to, by integrating from 0 to t, and using the monotonicity of f(x(t)):

$$f(x(t)) - f^* \leqslant \frac{1}{t} \int^t \left[f(x(u)) - f^* \right] du \leqslant \frac{1}{2t} \|x(0) - x^*\|^2 - \frac{1}{2t} \|x(t) - x^*\|^2 \leqslant \frac{1}{2t} \|x(0) - x^*\|^2.$$

 $f \to \min_{x,y,z}$ Gradient Flo

1. Simplest proof of monotonic decrease of GF:

$$\frac{d}{dt}f(x(t)) = \nabla f(x(t))^{\top} \frac{dx(t)}{dt} = -\|\nabla f(x(t))\|_2^2 \leqslant 0.$$

If f is bounded from below, then f(x(t)) will always converge as a non-increasing function which is bounded from below. It is straightforward, that GF converges to the stationary point, where $\nabla f=0$ (potentially including minima, maxima and saddle points).

2. If we additionaly have convexity:

$$f(x) \geqslant f(y) + \nabla f(y)^\top (x-y) \qquad \Rightarrow \qquad \nabla f(y)^\top (x-y) \leqslant f(x) - f(y)$$

3. Finally, using convexity:

$$\frac{d}{dt}[\|x(t) - x^*\|^2] = -2(x(t) - x^*)^\top \nabla f(x(t)) \leqslant -2[f(x(t)) - f^*]$$

4. Leading to, by integrating from 0 to t, and using the monotonicity of f(x(t)):

$$f(x(t)) - f^* \leqslant \frac{1}{t} \int^t \left[f(x(u)) - f^* \right] du \leqslant \frac{1}{2t} \|x(0) - x^*\|^2 - \frac{1}{2t} \|x(t) - x^*\|^2 \leqslant \frac{1}{2t} \|x(0) - x^*\|^2.$$

 $f \to \min_{x,y,z}$ Gradient Flo

1. Simplest proof of monotonic decrease of GF:

$$\frac{d}{dt}f(x(t)) = \nabla f(x(t))^{\intercal} \frac{dx(t)}{dt} = -\|\nabla f(x(t))\|_2^2 \leqslant 0.$$

If f is bounded from below, then f(x(t)) will always converge as a non-increasing function which is bounded from below. It is straightforward, that GF converges to the stationary point, where $\nabla f = 0$ (potentailly including minima, maxima and saddle points).

2. If we additionally have convexity:

$$f(x) \geqslant f(y) + \nabla f(y)^\top (x-y) \qquad \Rightarrow \qquad \nabla f(y)^\top (x-y) \leqslant f(x) - f(y)$$

3. Finally, using convexity:

$$\frac{d}{dt} \big[\|x(t) - x^*\|^2 \big] = -2(x(t) - x^*)^\top \nabla f(x(t)) \leqslant -2 \big[f(x(t)) - f^* \big]$$

4. Leading to, by integrating from 0 to t, and using the monotonicity of f(x(t)):

$$f(x(t)) - f^* \leqslant \frac{1}{t} \int^t \left[f(x(u)) - f^* \right] du \leqslant \frac{1}{2t} \|x(0) - x^*\|^2 - \frac{1}{2t} \|x(t) - x^*\|^2 \leqslant \frac{1}{2t} \|x(0) - x^*\|^2.$$

We recover the usual rates in $\mathcal{O}\left(\frac{1}{h}\right)$, with $t=\alpha k$.

Convergence analysis. PL case.

1. The analysis is straightforward. Suppose, the function satisfies PL-condition:

$$\|\nabla f(x)\|^2 \geq 2\mu(f(x) - f^*) \quad \forall x$$

Convergence analysis. PL case.

1. The analysis is straightforward. Suppose, the function satisfies PL-condition:

$$\|\nabla f(x)\|^2 \ge 2\mu (f(x) - f^*) \quad \forall x$$

2. Then

$$\frac{d}{dt} [f(x(t)) - f(x^*)] = \nabla f(x(t))^\top \dot{x}(t) = -\|\nabla f(x(t))\|_2^2 \leqslant -2\mu [f(x(t)) - f^*]$$

Convergence analysis. PL case.

2. Then

$$\frac{d}{dt} [f(x(t)) - f(x^*)] = \nabla f(x(t))^\top \dot{x}(t) = -\|\nabla f(x(t))\|_2^2 \leqslant -2\mu [f(x(t)) - f^*]$$

3. Finally.

$$f(x(t))-f^*\leqslant \exp(-2\mu t)\big[f(x(0))-f^*\big],$$

 $f \to \min_{x,y,z}$ Gradient Flow

Accelerated Gradient Flow

Accelerated Gradient Flow

Remember one of the forms of Nesterov Accelerated Gradient

$$\begin{aligned} x_{k+1} &= \ y_k - \alpha \nabla f(y_k) \\ y_k &= \ x_k + \frac{k-1}{k+2} (x_k - x_{k-1}) \end{aligned}$$

The corresponding ¹ ODE is:

$$\ddot{X}_t + \frac{3}{t}\dot{X}_t + \nabla f(X_t) = 0$$

Accelerated Gradient Flow

Define the *energy*

$$E(t) = t^2 \left(f(X(t)) - f^* \right) + 2 \left\| X(t) - x^* + \frac{t}{2} \dot{X}(t) \right\|^2.$$

A direct differentiation using the ODE yields $\dot{E}(t) \leq 0$ for all t > 0; hence E(t) is non-increasing. Because the second term is non-negative we obtain the convergence theorem

$$f(X(t)) - f^* \leq \frac{2 \|x_0 - x^*\|^2}{t^2} \ . \tag{AGF-rate}$$

Thus AGF enjoys the same $\mathcal{O}(1/t^2)$ rate that discrete NAG achieves in $\mathcal{O}(1/k^2)$ iterations. A similar argument with a restarted ODE gives an exponential rate for μ -strongly convex f.

How to model stochasticity in the continuous process? A simple idea would be: $\frac{dx}{dt} = -\nabla f(x) + \xi$ with variety of options for ξ , for example $\xi \sim \mathcal{N}(0, \sigma^2) \sim \sigma^2 \mathcal{N}(0, 1)$.

Therefore, one can write down Stochastic Differential Equation (SDE) for analysis:

$$dx(t) = -\nabla f\left(x(t)\right)dt + \sigma dW(t)$$

Here W(t) is called Wiener process. It is interesting, that one could analyze the convergence of the stochastic process above in two possible ways:

• Watching the trajectories of x(t)
